We give a simple, self-contained proof of the following basic fact [1, 2] in matching theory:

Theorem *Every bipartite regular multigraph is factorizable.*

Proof: Assume G to be a counterexample with the smallest number of edges. Then G is r-regular for some integer $r \geq 1$. Let $e = uv$ be any edge of G. In G, remove nodes u and v, then add a set of edges F as to obtain a bipartite multigraph G' which is r-regular. Note that $|F| < r$ and G' has less edges than G. By assumption G' contains r disjoint 1-factors. Since $|F| < r$, at least one of these 1-factors, say M', is disjoint from F. Therefore $M = M' \cup \{e\}$ is a 1-factor of G. Moreover $G \setminus M$ has less edges than G and is factorizable. But then G is factorizable. □

Note that the above proof does not use any alternating path argument.
